Luminaire

The invention relates to a luminaire comprising a reflector body with a reflecting portion provided with a coating.

Luminaires of the kind mentioned in the opening paragraph are used inter alia in ceiling lighting and for illuminating objects such as, for example, objects in a shop window, in a shop, in an exhibition space, for example for the illumination of art objects, or in a showroom, for example for the illumination of comparatively large objects, for example vehicles. Such a luminaire is further used for wall illumination so as to illuminate objects from the side, or as floor illumination, for example on theatrical stages, for the illumination of objects or persons. Said luminaire is also employed in outdoor environment. Said luminaire is further used as backlights for, for example, (picture) display devices such as, for example, (plasma addressed) liquid crystal displays, or video walls, and as office lighting, or as a luminaire for enhancing the appearance of an object.

International Patent Application WO-A 01/75358 describes a luminaire with a molded reflector body comprising a reflective coating with light reflective particles and a binder and having a reflecting portion side and an outer surface. The coating has a smooth optical wave guiding surface due to the absence of particles at its outer surface and to the light-transmission properties of the binder. Owing to these properties, the coating has a high degree of specular reflection, thereby both increasing the lumen output ratio and improving the light directional properties of the luminaire.

A drawback of the known luminaire is that the coating is sensitive to degradation reducing the lifetime of the luminaires.

The invention has for its object to eliminate the above disadvantage wholly or partly. According to the invention, a luminaire of the kind mentioned in the opening paragraph for this purpose comprises:

a reflector body with a reflecting portion provided with a coating based on an inorganic sol-gel system,

the coating comprising a light-transmitting binder,

the light-transmitting binder comprising light-reflecting particles,

the light-reflecting particles being chosen from a group formed by titanium oxide, aluminum oxide, halophosphates, calcium pyrophosphate and strontium pyrophosphate, and

the light-reflecting particles being surrounded by a skin layer for improving the reflection of the coating.

By basing the coating on an inorganic sol-gel system, the sensitivity of the coating for UV exposure and for high temperatures is reduced. As a consequence the sensitivity of the luminaire provided with such a coating is reduced, extending the lifetime of the luminaire according to the invention. In the known luminaire the coating is based on an organic system. In particular, the light-reflecting particles in the known luminaire are combined with a light-transmitting binder, said binder being a silicone binder, a fluoro-polymer or an acrylate. The measure according to the invention is notably suitable for outdoor luminaires.

The inorganic sol-gel process is a versatile solution process for making ceramic and glass materials. In general, the sol-gel process involves the transition of a system from a liquid "sol" (mostly colloidal) into a solid "gel" phase. Applying the sol-gel process, it is possible to fabricate ceramic or glass materials in a wide variety of forms: ultra-fine or spherical shaped powders, thin film coatings, ceramic fibers, micro-porous inorganic membranes, monolithic ceramics and glasses, or extremely porous aerogel materials.

The starting materials used in the preparation of the "sol" are usually inorganic metal salts or metal organic compounds such as metal alkoxides. In a typical sol-gel process, the precursor is subjected to a series of hydrolysis and polymerization reactions to form a colloidal suspension, or a "sol". Further processing of the "sol" enables one to make ceramic materials in different forms. Thin films can be produced on a piece of reflecting portion by spin-coating or dip-coating. When the "sol" is cast into a mold, a wet "gel" will form. With further drying and heat-treatment, the "gel" is converted into dense ceramic or glass articles.

The binder, which transmits visible light, forms a transparent, light-guiding layer over the light-reflecting particles and over the reflector body. Diffuse and specular reflection of visible light occurs at the coating. The relatively high degree of specular reflection enables that substantially all light originating from a light source issues from the

luminaire to the exterior directly or after only one reflection. This results in relatively low loss of light loss owing to reflection against the coating. The luminaire according to the invention has a comparatively high light output ratio. The luminaire according to the invention is suitable for use in accent lighting because of its coating with a high degree of specular reflection.

Choosing light-reflecting particles from the group formed by titanium oxide, aluminum oxide, halophosphates, calcium pyrophosphate and strontium pyrophosphate are very suitably for the coating. These light-reflecting particles can be very well combined with the light-transmitting binder, for example a silicone binder, a fluoro polymer (for example THV 200), or acrylate. A luminaire provided with a coating of such a composition of particles and binder on its reflector portion has very good light-reflecting and beam-shaping properties. Preferably, the size of the light-reflecting particles ranges from 100 to 500 nm.

By surrounding the light-reflecting particles by a skin layer causes a further improvement in the specular reflection of the coating. To improve the specular reflection still further, the skin layer and the light-reflecting particles preferably have different refractive indices. Preferably, the skin layer comprises silicon oxide or aluminum oxide. SiO_2 and Al_2O_3 are suitable materials for use as skin layer surrounding the light-reflecting particles.

In a preferred embodiment of the luminaire the inorganic sol-gel system is a silica-based sol-gel system. The application of silica sol-gel systems is well known in the art. Suitable starting materials in silica sol-gel systems are methyltrimethoxysilane (MTMS) or tetraethylorthosilicate (TEOS).

Preferably, the light-transmitting binder comprises silicon oxide particles. By adding silicon oxide particles to the light-transmitting binder it becomes possible to make relatively thick coatings. By way of example so-called Ludox^{TM} particles (colloidal silica particles) may be employed. Preferably, the size of the silicon oxide particles ranges from 10 to 50 nm.

With the coating system used in the luminaire according to the invention relatively thick coatings can be realized. A preferred embodiment of the high-pressure discharge lamp assembly is characterized in that the thickness of the coating ranges from 1 to 200 μm. Preferably, the thickness of the coating ranges from 10 to 100 μm. Such thicknesses cannot be realized in a luminaire based on organic coatings, like in the known luminaire.

Metal is a very suitable material for the reflecting portion of the reflector body. Preferably, the metal comprises aluminum. The combination of an aluminum reflecting

portion with a light-transmitting binder comprising silicon oxide particles is very suitable because of the match between the thermal expansion coefficients

In a preferred embodiment of the luminaire the light-transmitting binder comprises a stabilizing agent. Such a stabilizing agent improves the stability of the coating.

These and other aspects of the invention are apparent from and will be elucidated with reference to the embodiments described hereinafter.

In the drawings:

Fig. 1 shows an embodiment of a luminaire according to the invention in cross-section, and

Fig. 2 shows a detail of the coating for a luminaire according to the invention;

The Figures are purely diagrammatic and not drawn to scale. Notably, some dimensions are shown in a strongly exaggerated form for the sake of clarity. Similar components in the Figures are denoted as much as possible by the same reference numerals.

Figure 1 schematically shows an embodiment of a luminaire according to the invention in cross-section. The luminaire comprises a reflector body 9 with a reflecting portion 2. Preferably, the reflecting portion 2 of the reflector body 9 comprises a metal. In a favorable embodiment the metal comprises aluminum. The reflector body 9 is provided with a coating 5 based on an inorganic sol-gel system. Preferably, the inorganic sol-gel system is a silica-based sol-gel system.

In the example of Figure 1, the luminaire further comprises a diffuser 3 which is positioned in front of a light emission window 4 of the luminaire 1. In addition, the reflective portion 2 and the diffuser 3 are both coated with the coating 5. In an alternative embodiment the coating 5 may alternatively be provided solely on the reflective portion 2. In Figure 1 the luminaire 1 is provided with contact means 6. In addition, Figure 1 shows by way of example four (tubular) low-pressure mercury discharge fluorescent lamps 6a are accommodated in the contact means 6, for example PLS 11W. Other suitable lamps are high-pressure discharge lamps, such as a CDM or a SON. The lamps 6a are positioned in a longitudinal direction perpendicular to the plane of the drawing and along the light emission window 4. During operation of the lamps 6a, light beams 7 originating from the lamps 6a fall upon the coating 5 and are either reflected by the coating 5 or transmitted through the coating

5 and the diffuser 3. At each reflection 8 of the light beams 7 at the coating 5 some scattering of the light beams 7 occurs, eventually resulting in a homogeneous distribution of light. Finally upon transmission of the light beams 7 through the diffuser 3 a final scattering of the light beams 7 takes place. As a result an object is illuminated homogeneously by the luminaire 1.

Figure 2 schematically shows a detail of the coating for a luminaire according to the invention. The coating 5 comprises a light-transmitting binder 11. Preferably, the light-transmitting binder 11 comprises a stabilizing agent. The light-transmitting binder 11 comprises light-reflecting particles 10. The light-reflecting particles 10 are chosen from a group formed by titanium oxide, aluminum oxide, halophosphates, calcium pyrophosphate and strontium pyrophosphate. Preferably, the size of the light-reflecting particles 10 is in the range from 100 to 500 nm.

In Figure 2, the light-reflecting particles 10 are surrounded by a skin layer 14 for improving the reflection of the coating 5. Preferably, the skin layer 14 comprises silicon oxide or aluminum oxide. In addition, the light-transmitting binder 11 further comprises silicon oxide particles 20. Preferably, the size of the silicon oxide particles 20 is in the range from 10 to 50 nm.

The thickness of the coating 5 is in the range from 1 to 200 μm. Preferably, the thickness of the coating 5 is in the range from 10 to 100 μm.

By basing the coating on an inorganic sol-gel system, the sensitivity of the coating for UV exposure and for high temperatures is reduced. As a consequence the sensitivity of the luminaire provided with such a coating is reduced, extending the lifetime of the luminaire according to the invention.

A typical example of a luminaire suitable for application at high temperature and resistant to UV exposure is a coating based on silica-based sol-gel system starting with of methyltrimethoxysilane (MTMS) in combination with colloidal silica particles, for instance Ludox TM-50. The light-reflecting particles comprise either titanium oxide (TiO_2) or aluminum oxide Al_2O_3 to improve the reflection of the coating.

Coatings based on MTMS/Ludox are very suitable, because the thermal expansion coefficient, expressed in α, matches that of the aluminum substrates in the luminaires ($\alpha_{MTMS/Ludox} = 20$ ppm/K and $\alpha_{Al} = 24$ ppm/K). This match in thermal expansion coefficient enables the manufacture of sufficiently thick coatings. A thick coating provides a relatively high total reflection. The silica-base sol-gel based sol-gel system in the luminaire

according to the invention is temperature resistant up to 400-450°C. In the known luminaire based on an organic binder system, the coatings cannot be applied above 150°C.

In addition, the silica-base sol-gel based sol-gel system in the luminaire according to the invention withstands UV-A and UV-B radiation to a high degree. By providing TiO_2 particles with a skin layer of SiO_2 degradation of methyl groups by the photo-catalytic activity of TiO_2 particles is largely prevented.

A coating in a luminaire based on an inorganic silica-based sol-gel system according to the invention is compared to a coating in the known luminaire based on an organic binder system. The reflectance at 550 nm is measured as a function of time when the coating is exposed to UV-B radiation (approximately 0.6 W/m^2/nm; temperature = 70°C). In addition, the color change ΔE is measured as a function of time when the coating is exposed to UV-B radiation. The color change ΔE represents the influence of the various color components and is defined as follows:

$$\Delta E = \sqrt{(\Delta L)^2 + (\Delta a)^2 + (\Delta b)^2},$$

wherein ΔL is the balance between black and white (if ΔL>0 then more whitish), Δa is the balance between green and red (if Δa>0 then more reddish), and Δb is the balance between blue and yellow (if Δb>0 then more yellowish).

Table I summarizes the results of the degradation as a function of time.

Table I Degradation of the reflectance and color change ΔE as a function of time for coatings exposed to UV-B radiation

hours UV-B radiation	coating in a luminaire according to the invention based on an inorganic silica-based sol-gel system		coating in the known luminaire based on an organic binder system	
	reflectance	color change ΔE	reflectance	color change ΔE
0	96.5	0	95.9	0
100	96.5	0.08	95.9	0.15
200	96.5	0.10	95.7	0.28
400	96.4	0.11	94.2	0.68
1000	95.8	0.13	92.0	1.2
2000	95.1	0.17	89.9	2.6

It can be learned from Table I that coatings based on inorganic silica-based sol-gel systems in luminaires according to the invention are highly resistant to UV-radiation.

It should be noted that the above-mentioned embodiments illustrate rather than limit the invention, and that those skilled in the art will be able to design many alternative embodiments without departing from the scope of the appended claims. In the claims, any reference signs placed between parentheses shall not be construed as limiting the claim. Use of the verb “comprise” and its conjugations does not exclude the presence of elements or steps other than those stated in a claim. The article “a” or “an” preceding an element does not exclude the presence of a plurality of such elements. The invention may be implemented by means of hardware comprising several distinct elements, and by means of a suitably programmed computer. In the device claim enumerating several means, several of these means may be embodied by one and the same item of hardware. The mere fact that certain measures are recited in mutually different dependent claims does not indicate that a combination of these measures cannot be used to advantage.

CLAIMS:

1. A luminaire comprising:

a reflector body (9) with a reflecting portion (2) provided with a coating (5) based on an inorganic sol-gel system,

the coating (5) comprising a light-transmitting binder (11),

the light-transmitting binder (11) comprising light-reflecting particles (10),

the light-reflecting particles (10) being chosen from a group formed by titanium oxide, aluminum oxide, halophosphates, calcium pyrophosphate and strontium pyrophosphate, and

the light-reflecting particles (10) being surrounded by a skin layer (14) for improving the reflection of the coating (5).

2. A luminaire as claimed in claim 1, characterized in that the light-transmitting binder (11) comprises silicon oxide particles (20).

3. A luminaire as claimed in claim 2, characterized in that the size of the silicon oxide particles (20) ranges from 10 to 50 nm.

4. A luminaire as claimed in claim 1 or 2, characterized in that the inorganic sol-gel system is a silica-based sol-gel system.

5. A luminaire as claimed in claim 1 or 2, characterized in that the skin layer (14) comprises silicon oxide or aluminum oxide.

6. A luminaire as claimed in claim 1 or 2, characterized in that the size of the light-reflecting particles (10) ranges from 100 to 500 nm.

7. A luminaire as claimed in claim 1 or 2, characterized in that the thickness of the coating (5) ranges from 1 to 200 μm.

8. A luminaire as claimed in claim 7, characterized in that the thickness of the coating (5) ranges from 10 to 100 μm.

9. A luminaire as claimed in claim 1 or 2, characterized in that the reflecting portion (2) of the reflector body (9) comprises a metal.

10. A luminaire as claimed in claim 9, characterized in that the metal comprises aluminum.

11. A luminaire as claimed in claim 1 or 2, characterized in that the light-transmitting binder (11) comprises a stabilizing agent.

ABSTRACT:

A luminaire has a reflector body (9) with a reflecting portion (2) provided with a coating (5) based on an inorganic sol-gel system, preferably a silica-base sol-gel system. The coating comprises a light-transmitting binder. The light-transmitting binder comprises light-reflecting particles. The light-reflecting particles are chosen from a group formed by titanium oxide, aluminum oxide, halophosphates, calcium pyrophosphate and strontium pyrophosphate. The light-reflecting particles being surrounded by a skin layer for improving the reflection of the coating. Preferably, the skin layer comprises silicon oxide or aluminum oxide. Preferably, the light-transmitting binder comprises silicon oxide particles.
